

**Construction of Facade:**

The steel tubes are placed and secured into place first as these are the material that supports the facade's weight. They contain a hole in which the spider support is placed at regular intervals. The glass panels are then placed, usually in groups of four.

**Function of Facade:**

The facade is made to be both a barrier from the weather, so the rain line in which the silicone sealant achieves a water tight seal between the panels. The insulative addition to the tempered glass is also designed to maintain minimal heat lost using a single material. The steel supports only the glass in this example.
